

Tableau Assessment - Sales Reporting Brief

Role-based assessment for students acting as a junior data analyst

Professional Context

You have joined a retail company as a junior data analyst. The sales team wants a simple Tableau report that helps them review sales activity, customer activity and product performance. Your task is to use the three provided datasets - **customers.csv**, **products.csv** and **orders.csv** - to build a clean Tableau workbook, create a dashboard for business users, and publish the finished work for review.

The data supports this task well. The orders table contains the transaction detail, including order number, order date, region, payment type, price, cost and quantity. The customers file adds customer names and customer segment, while the products file adds product name and product category. The order dates run from **23 Jun 2022** to **18 Jun 2025**, which makes a time-based sales chart possible. Region analysis is possible because the data includes location fields, and customer segment analysis is possible because values such as **Consumer**, **Corporate**, **Home Office** are already available.

What the student needs to do in Tableau

Open Tableau Desktop or Tableau Public and connect to the three CSV files. On the Data Source page, use **customer_id** to connect the orders data to the customers data, and use **product_id** to connect the orders data to the products data. You may use relationships or joins depending on the Tableau version available, but the result must combine the order records with the customer and product information correctly. Check that the date field is recognised as a date and that price, cost and quantity are numeric fields. Remove duplicate rows if any are found.

Create one calculated field called **Full Name** by combining customer first name and customer last name. Then create only three calculated measures so the task remains focused and manageable. The required calculated measures are **Total Sales**, **Total Orders** and **Total Quantity**. Total Sales should be based on price multiplied by quantity. Total Orders should count the order number. Total Quantity should sum the quantity field.

Required workbook, sheet and dashboard names

Item	Required name
Workbook	Sales Insights Workbook
Worksheet 1	Total Sales
Worksheet 2	Total Orders
Worksheet 3	Total Quantity Sold
Worksheet 4	Sales by Product Category
Worksheet 5	Top 10 Customers by Total Sales
Worksheet 6	Orders by Region
Worksheet 7	Sales by Order Date
Worksheet 8	Customer Product Detail
Dashboard	Sales Analysis Dashboard

Worksheets and dashboard to create

The workbook should contain eight worksheets and one dashboard. The first three worksheets, **Total Sales**, **Total Orders** and **Total Quantity Sold**, should each be created as simple KPI-style sheets. These sheets will later be used as number tiles on the dashboard. The fourth worksheet, **Sales by Product Category**, should be a bar or column chart comparing Total Sales across product categories.

The fifth worksheet, **Top 10 Customers by Total Sales**, should be a bar chart using the Full Name field and the Total Sales measure. The sixth worksheet, **Orders by Region**, should compare order counts across the available regions, which include **Central Africa**, **North Africa**, **South Africa**, **West Africa**. The seventh worksheet, **Sales by Order Date**, should be a line chart showing how Total Sales changes across the order dates. The eighth worksheet, **Customer Product Detail**, should be a text table that includes Full Name, product name and one of the required measures.

Place these sheets on one dashboard called **Sales Analysis Dashboard**. Arrange the three KPI sheets across the top. Under them, place **Sales by Product Category** and **Top 10 Customers by Total Sales** as the main comparison charts. Below or beside these, add **Orders by Region** and **Sales by Order Date**. Include the **Customer Product Detail** sheet in a smaller supporting area. If desired, add one or two simple filters such as Region or Customer Segment.

Formatting and publishing requirement

The finished workbook should be formatted clearly and consistently. Tableau does not use Power BI themes, so in this assessment the student should create a simple consistent style manually by using the same font family, one accent colour, matching title formatting and a clean dashboard layout with even spacing. All sheet titles and the dashboard title should be entered exactly as given in this brief.

Once the workbook is complete, publish it to **Tableau Public** if Tableau Public is being used, or publish it to your institution's Tableau Server or Tableau Cloud environment if that is available. The final submission should show the workbook with all eight worksheets completed, the dashboard created with the required name, and the published link or screenshot provided as evidence of completion.

Final submission expectation

The final submission should demonstrate that the student can connect multiple CSV files, combine data correctly in Tableau, create one calculated field, create three simple calculated measures, build eight worksheets, assemble them into one dashboard, format the workbook consistently, and publish the final output. The task should be presented professionally with correct naming, readable charts and a clear dashboard layout.
